Introduction

Data science is the study, development, and practice of using reproducible and transparent processes to generate insight from data [1–4]. With roots in statistics and computer science, data science educators draw on many of the teaching strategies used in those fields [5–7]. However, data science is a distinct discipline with its own unique challenges and opportunities for teaching and learning. Here, we collate and present ten simple rules for teaching data science, piloted by leading data science educators in the community and successfully applied in our own data science classroom.

Rule 1: Teach data science by doing data analysis

The first rule is teaching data science by doing data analysis. This means that in your first data science lesson, not in your third lesson, not in your 10th lesson, not at the end of the semester, but in your first data science lesson, have the students load some data, perform some simple data wrangling, and create a data visualization. We call this the “let them eat cake” approach to teaching data science [8].

Why do we suggest this? Because, just like eating cake, it’s extremely motivating to students. At first, students sign up for a data science course or workshop because

they're interested in asking and answering questions about the world using data. They
 likely don't yet have sufficient knowledge to care deeply about detailed, technical
 aspects, such as object data types, whether to use R versus Python, or, if using R,
 whether to opt for the tidyverse or base R. As a result, we should show them something
 interesting very early on to hook them. After they are hooked, they will be begging you
 to answer questions about the detailed, technical aspects you intentionally omitted. An
 example of this is shown in Fig 1; code from the first chapter of Data Science: A First
 Introduction [4]. In this first chapter, we ask learners to load data from a CSV file and
 perform introductory data wrangling using filtering, arranging, and slicing. Finally,
 create a plot to answer a question about indigenous languages in Canada: how many
 people living in Canada speak an indigenous language as their mother tongue? Other
 leading data science educators who advocate and practice this rule include Wang and
 colleagues [9], David Robinson in his introductory online Data Science course [10,11],
 and Jenny Bryan [12], who summed this up nicely in a tweet “[...] I REPEAT, do not
 front-load the ‘boring’, foundational stuff. Do realistic and non-boring tasks and work
 your way down to it.”

Figure 1. Example code from the first chapter of *Data Science: A First Introduction* [4] that gets students doing data analysis on day one.

Rule 2: Use participatory live coding

The second rule is to use participatory live coding. This means that when you are
 working with code in the classroom, instead of showing it on a static slide or just
 running it in an executable slide or an IDE, actually type the code and narrate it as you
 teach. Have the participants follow along as well. The reason is that it demonstrates
 your best practices for processes and workflows, topics that are important in practice

but, unfortunately, are often just an afterthought in teaching computational subjects. 39
You can discuss why you're approaching things differently as you go. You are also likely 40
to make mistakes as you live-code, and that's actually a good thing. It helps you appear 41
human to students because they, too, will make mistakes. More importantly, it allows 42
you to demonstrate how you approach debugging to solve code problems, which they 43
can leverage in their homework and later in their work outside the course. Participatory 44
live coding also slows you down, so you don't go too fast for the students. This 45
pedagogy originates from the "I do, we do, you do" method of knowledge transfer [13], 46
and its application in teaching programming was pioneered by The Carpentries, a global 47
nonprofit (<https://carpentries.org>). Best practices for doing this have been refined and 48
shared as ten quick tips by Nederbragt and colleagues [14]. 49

Rule 3: Give tons and tons of practice and timely 50 feedback 51

The third simple rule is to give tons and tons of practice. Give the learners many, many, 52
many problems to solve, probably many, many, many more than you think they might 53
need. The reason for this is that repetition leads to learning [15]. That's not just in 54
humans; it is more fundamental than that. In the field of animal behavior across the 55
animal kingdom, repetition is found to lead to learning [16,17]. Similarly, students need 56
to practice tasks many times to understand and then perform them effectively. For 57
example, when teaching students to read data from a file, don't just give them one file 58
to read; instead, have them work with six different variants of a very similar file. With 59
this approach, students have to investigate each file in detail, including checking the file 60
type, column spacing, whether there's metadata to skip, whether there are column 61
names, etc. In our courses, they will complete these six variants in an in-class 62
worksheet, a lab assignment, and a quiz. Meaning that by the end of the course, they 63
will have practiced this skill over 15 times. Many excellent data science educational 64
resources use this pedagogy, including software packages (e.g., the swirl R package [18]), 65
online courses (e.g., Kaggle Learn [19]), and popular textbooks (e.g., R for Data Science 66
[20]). For those new to designing practice exercises for data science, we recommend 67

looking at the “Exercise Types” chapter of *Teaching Tech Together: How to Make your lessons work and build a teaching community around them* by Greg Wilson [21].

When giving lots of practice, pair it with timely feedback. Practice without feedback has limited value. So, how can we provide a wealth of timely feedback, especially with our limited teaching capacity and resources? One way we can do this is through automated software tests. In data science, many of the problems we assign to students involve writing code. As a consequence, we can write software tests that provide feedback to students, letting them know when they give a wrong answer in a particular way, as well as providing a gentle, helpful nudge to solve the problem in a different way. Fig 2 shows an example of this in practice. Here, students were given some ggplot code in a Parsons problem format (the lines of code were given in the wrong order, and the students needed to rearrange them to the correct order). In this example, a student has rearranged the code, but not entirely correctly, and as a result, a plot is created, but it’s not quite what we expect. Without timely feedback, the student might not realize that there’s a problem with their code until much later, or not at all if they fail to check the feedback and solutions after the assignment is graded and grades are returned (often days or weeks later). Automated software testing can provide timely feedback while students’ focus and attention are on the topic being learned and practiced. This pedagogy was first developed and used for teaching programming in computer science courses [reviewed in 21] and is now being adopted in data science courses. There are now many wonderful and popular software packages for this in the context of data science, including the learnr R package [22] for R code, and the NBgrader [23] and Otter Grader [24] software packages, which work for both R and Python code.

Rule 4: Use tractable or toy data examples

Our fourth simple rule is to use tractable or toy data examples when introducing a new tool, method, or algorithm to students. Tractable or toy data sets have a countable number of elements, which can fit in our working memory. This allows students to track the progression of everything through the algorithm’s steps, see how the elements are manipulated, and gain a deeper understanding of these concepts. For example, in one of

Figure 2. Example of automated software test feedback to students.

our courses, we use the Palmer penguins data set [25] to introduce the students to k-means clustering. Instead of giving them the entire data set, which contains hundreds of observations, we first subset it to just a handful. Then we can walk the students through what happens to these observations at each step of the algorithm, building an understanding and intuition for the algorithm. Inspiration from this comes from Jenny Bryan's great dplyr joins cheat sheet [26]. In her cheat sheet, she teaches all the various joins from the dplyr package [27]. This is a difficult topic for students to understand and memorize, and when instructors teach this with large data sets, it is really hard for students to get an idea of what's going on. To make matters worse, all of these joins are also similarly named (e.g, left join, right join, inner join, outer join, etc). To address this issue, Jenny's cheat sheet uses two toy data sets on superhero comic characters and publishers. The superhero dataset has only 7 rows and 4 columns, while the publisher dataset has 3 rows and 2 columns. These data sets are small enough. The cheat sheet then outlines all the possible joins, narrating and displaying the output of each. To address this issue, Jenny Bryan's cheat sheet uses two toy data sets on superhero comic characters and publishers. The cheat sheet outlines all the possible joins, narrating and displaying the output of each. The superhero dataset has only 7 rows and 4 columns, while the publisher dataset has 3 rows and 2 columns. These data sets are small enough to fit in learners working memory, making the joins tractable and much easier to

understand.

116

It is, of course, not feasible to keep learners interested and motivated to learn more if we rely solely on toy datasets. So, once students have a conceptual understanding of the tool, method, or algorithm being taught, we can move on to using real, rich datasets, which is our next rule.

117

118

119

120

Rule 5: Use real and rich, but accessible data sets

121

After you've helped students develop a conceptual understanding of the new tool, method, or algorithm you are teaching, the next step is to have students apply it to realistic questions and real, rich data. However, as you're doing this, it is critical to ensure that the dataset is also accessible to all your learners. The question, as well as the observations (i.e., rows) and variables (i.e., columns) in the dataset, must be things that your learners can quickly understand. This can easily become an expert blind spot for us when we are teaching, especially if we have training in a particular domain. For example, one of the authors, who is trained in the biological sciences, might think that using a deep sequencing data set would be a great and motivating example for a particular algorithm we want to teach students. However, this thought likely stems from the author's deeper understanding of biological processes, which, in this example, gives them an expert blind spot. Given that, if learners do not have similar background knowledge, that dataset might not be appropriate. It might introduce too much cognitive load for the students, to the extent that they cannot focus on the task at hand — refining their understanding and application of the tool, method, or algorithm being taught. We do not want to use up our students' limited cognitive resources to understand what the dataset is about. Instead, we want to use something that all our learners can easily understand, including what the observations are and what the columns represent. One example from one of the courses that we teach uses Canadian census data about the languages spoken in Canada across different regions [28]. Other examples include the Gapminder [29] and UN Votes [30] data sets. These are particularly nice examples because they contain hundreds of observations; however, the observations are something most people can understand: a country, a year, a population,

136

137

138

139

140

141

142

143

144

a vote, etc. And with such a dataset, we can ask questions that most learners are 145
interested in, because everyone has grown up in at least one country, and possibly more, 146
in their lifetime. And we all grew up at different times in history. These lived 147
experiences make us generally knowledgeable and interested in asking questions about 148
the datasets. There are many more real and rich data sets that are accessible and 149
usable. The main point here is that it shouldn't take your students long to understand 150
the data set, because a deep understanding of it isn't what you are trying to teach at 151
that moment. It can also be helpful to bring in data sets that reflect your learners' local 152
context (e.g., country, region, culture) and/or current events to increase engagement and 153
relevance. It can be difficult to find such data sets in a timely manner, but it's often 154
worth the effort for learners to connect what they are learning in their data science 155
course to what's happening in their own lives and communities outside the classroom. 156

Rule 6: Provide cultural and historical context 157

Our sixth simple rule is to provide a cultural and historical context for what you're 158
teaching. For example, when teaching how to use a new software tool or a new feature 159
of a tool that students already know how to use, and things do not seem optimally 160
designed from the learner's perspective, it's really helpful to explain why they are that 161
way. If you give the design and historical context, for example, saying people thought 162
about this when they built the tool and decided this was the best way to implement it 163
for reasons X, Y, and Z, it helps the students understand that software tools are built 164
by humans, and so they are going to be influenced by humans' perspective, human 165
history, and human culture. Furthermore, it helps prevent frustration or annoyance 166
with the software because they can rationalize why it works the way it does. We believe 167
it is crucial to help prevent these frustrations or annoyances, as we have observed that, 168
for some learners, they can become significant barriers and lead to a dislike or avoidance 169
of a particular piece of software. 170

For example, when we teach the programming language R [31] using the suite of 171
tidyverse R packages [32]. Learners observe that these packages heavily use unquoted 172
column names when referencing data frame columns in their function calls. That is 173

really strange when you come from other programming languages, as most other
174
programming languages require quoted strings when referencing object attributes
175
(which is what a data frame column is). This can also make writing functions that
176
utilize tidyverse functions a bit more challenging due to issues with indirection. For
177
learners with experience in Python, Java, or C, this might initially seem like a really
178
bad idea. However, once they learn that R and the suite of tidyverse R packages were
179
written by statisticians for performing data analysis and graphics [31,32], and that they
180
designed the language and packages with the expectation that much of the users time
181
would be frequently typing things into the console or running code interactively, it
182
makes a lot more sense that they would want to minimize the amount of typing and
183
tracking of opening and closing quotations for their users. Doing this minimizes the
184
potential syntax errors that could be introduced by errors in forgetting to open or close
185
quotations.
186

Another example comes from the use of the arrow (`<-`) as an assignment operator in
187
R, which may seem odd to some learners as it uses two characters. Again, however,
188
when given the historical context that R was derived from another programming
189
language named S, and S was inspired by another programming language, APL, that
190
was designed for a particular keyboard with one key mapped to the assignment operator
191
[33], it makes a lot more sense as to why that design choice was made. Design and
192
historical contexts help learners understand the rationale behind different design choices,
193
allowing them to see choices they might not initially agree with as excellent within these
194
contexts. As an aside, for those interested in learning more about the history of the R
195
programming language, see the “History and Overview of R” chapter in Roger Peng’s *R*
196
programming data science book [34].
197

Rule 7: Build a safe, inclusive, and welcoming 198 community 199

The next rule is to build a safe, inclusive, and welcoming community. If we were to
200
rewrite this paper, we would probably move this to rule number one, given that this is
201
the first thing you need to do when teaching any subject. The reason is that people
202

don't learn effectively when they don't feel psychologically safe. Psychological safety is
203 the belief that one can express oneself, through speech or actions, without fear of
204 negative consequences or feedback [35]. If learners do not feel safe asking questions
205 without being made to look or feel dumb, they are not going to ask questions, and they
206 are not going to be engaged [36]. If they don't feel safe from negative perceptions about
207 their intelligence, discrimination, or harassment in the classroom (or related spaces such
208 as office hours, course forums, study groups, etc.), they may become so disengaged that
209 they even stop showing up. Thus, creating safe, inclusive, and welcoming learning
210 environments is crucial for effective learning, and as instructors, we have a responsibility
211 to establish scaffolding and guidelines that facilitate this. One thing we do in our
212 courses is establish a course code of conduct, which holds a place of prevalence in the
213 classroom and related learning spaces. At the beginning of a new course, we take time
214 in the first class to present our code of conduct to the learners. The codes of conduct we
215 use are very explicit. They discuss expected behaviors, behaviors that will not be
216 tolerated, the process for reporting violations, and the consequences for violating these
217 rules. We also ensure that there are multiple ways to report violations, to support
218 students in the unlikely event that the instructor is the one violating the code of
219 conduct. It is also important that when a violation is reported, it be taken seriously and
220 acted upon in a timely manner. No student concern should ever be ignored or brushed
221 off. For instructors seeking to establish a code of conduct for their course, we
222 recommend examining existing codes of conduct from other organizations and tailoring
223 them to your specific context. One particularly good example is The Carpentries' code
224 of conduct (https://docs.carpentries.org/topic_folders/policies/code-of-conduct.html).
225

Rule 8: Use checklists to focus and facilitate peer learning

Rule number eight is to use checklists to focus and facilitate peer learning. A
228 well-documented pedagogical best practice is for peers to learn from each other [37].
229 One implementation of this is peer review. However, peer review can be particularly
230 challenging if you haven't done it before, or if it involves reviewing something new that
231

you are still learning. So what can we do as instructors to facilitate this practice for our
232 learners? Given that we are well-practiced at creating rubrics for grading student work,
233 we can use our existing rubrics as a starting point for drafting peer-review checklists.
234 Why checklists? Checklists can help ensure complex tasks are completed successfully
235 and have been used in safety-critical systems (such as aviation, surgery, or nuclear
236 power). They can be particularly helpful for complex tasks, as well as for repetitive ones
237 that are consequently boring [38]. For these reasons, checklists have recently been
238 adopted in scientific (e.g., PLoS journals, Nature Ecology & Evolution, Journal of Open
239 Source Education, Journal of Open Source Software) and software (e.g., ROpenSci,
240 PyOpenSci) publishing to help ensure that reviewers and editors increase transparency,
241 decreases bias and call attention to essential elements of reviews that are often
242 overlooked [39]. As reviewers for some of these journals and organizations, the authors
243 have found checklists extremely helpful for focusing our attention on the most
244 important elements of a review and for ensuring we don't miss anything. We believe
245 this idea also has value in training data science students. **S1 File** shows an example of
246 a data analysis review checklist that we have used in our data science courses. It serves
247 to communicate the aspects that we, as educators, believe are important for the
248 assessment to be completed to a high quality. In addition to checking off the checklist
249 items, students are also asked to provide written comments and feedback. This checklist
250 helps focus students' comments and feedback on the items they were unable to check off.
251 For example, if there were issues with the software tests (e.g., they were missing) and
252 issues with the discussion section (e.g., they did not mention any limitations of the
253 analysis), they would not check those boxes, and that would help focus their review
254 comments on critical feedback about the issues with those sections.
255

Rule 9: Teach students to work collaboratively

256

Data science is a highly collaborative discipline. Data scientists often work in teams or,
257 at a minimum, need to collaborate with other stakeholders (e.g., domain experts,
258 project managers, clients). Consequently, it is essential that we teach our students to
259 work collaboratively. To do this effectively, we must teach them both the technical tools
260

and skills necessary for collaboration (e.g., version control tools, such as Git and GitHub, project boards), as well as the social practices that make collaboration effective (e.g., active listening, giving critical feedback, code review). We must also give them opportunities to practice collaboration. Practice should occur at increasing levels of complexity, starting with smaller in-class activities, such as think-pair-share and pair programming, progressing to larger group assignments, and then culminating in projects.

When getting students to work collaboratively on longer-scale assignments and projects, it is important to scaffold good collaboration practices into your assignment or project expectations (and grading). In our project courses, we have students spend the first working session almost entirely on group formation activities. In this session, we have them participate in icebreaker activities to get to know each other and build trust. After that, we get them to create a teamwork contract that outlines their expectations for the project and how they will work together. During the project, we have them hold regular team check-ins (e.g., stand-ups, meetings) and use project boards to track their tasks and progress. At the end of the project, we have them do a teamwork reflection activity to reflect on what went well and what could be improved. As seasoned collaborators, we often take these practices for granted. However, for students new to collaboration, these practices are often missed, and as a result, collaboration frequently breaks down. Even with these scaffolds in place, we still see some groups struggle with collaboration. To manage this, we recommend discussing with students the importance of expecting, rather than avoiding, conflict, and developing, as a group, a plan ahead of time for how to manage it when it arises.

Rule 10: Have students do projects

Our final simple rule is to have students complete projects — create an entire data product (ideally, on a topic of their choosing, if feasible) from beginning to end (or from “nachos to cheesecake,” to quote Jenny Bryan). Projects can be done individually or in groups. The main point is that students have the opportunity to experience the entire data science workflow. Doing project work is important because it really helps motivate students. It also provides students with valuable experience in dealing with the

messiness of real data (we all know that in the real world, data is often quite messy).
Additionally, courses typically focus on just a small part of a data analysis workflow.
For example, they might focus on data visualization, data wrangling, or modeling. But
in a project, they get to see how all these pieces fit together in a more realistic scenario.
This is critical training for any aspiring data scientist [40].

From the instructor's perspective, however, projects can feel daunting, particularly
when student numbers are large and teaching resources are not. One way to make
projects more feasible is to scope them. You may want to limit the project to a
particular topic, or have students choose a data set from a given list, use a specific
method, or employ a particular programming language. Doing this provides some
consistency in grading and allows you to create a rubric that applies to all projects. An
example of a scoped project from a course on collaborative software development in
data science that we teach asks students to create a Python package with n functions,
where n is the number of students in the project group. The functions must be related
to a common theme and fall under the umbrella of data science. Students must utilize
the packaging tools and collaborative practices taught in our course. This kind of
project is very feasible to grade because its scope is well-defined and limited. However,
it also allows students to be creative and work on something they are interested in.
Another way to scope projects is to have students work on projects that use related to
their own research or thesis work, but utilize the data science concepts, tools or
techniques being taught in the course. This is particularly relevant for graduate
students enrolled in data science courses as part of their degree program. For example,
in the UBC STAT 545 course developed by Jenny Bryan, students learn new data
science concepts and skills using a tractable dataset in the classroom (e.g., the
Gapminder dataset), but their project involves applying the newly acquired concepts
and skills to their own research or thesis work. The project complexity builds
week-by-week along with what is being taught in the course syllabus. Again, this
approach makes grading more feasible by creating homogeneity with what data science
techniques and methods the students use in their projects, and students get to work on
something they are deeply interested in and motivated to do.

Conclusion

320

This list of ten simple rules for teaching data science is by no means exhaustive, but we
hope it provides a useful starting point for new data science educators. This list was
curated from our own experiences teaching data science, as well as from what we've seen
other leading data science educators practice.
